Reference

Performance

- to speed up programs by arranging that different parts of the program are run in parallel on different machines.

Reliability

- to make fault tolerant systems by structuring the system to be replicated on several machines: if one fails the computation continues on another machine.

Scalability

- resources on a single machine tend to be exhausted;
- to add another computer means to double the resources.

Intrinsically Distributed Applications

- e.g., chat systems, multi-user games, ...

Distributed Programming in Erlang Models of Distribution

Distribution in Erlang

Walter Cazzola

Distributio

name serv

cookie syst socket-Base lib_ckan

Reference

Erlang provides two models of distribution: distributed Erlang and socket based distribution

Distributed Erlang

- applications run on a set of tightly coupled computers called <u>Erlang</u> nodes;
- processes can be spawned on every node, and
- apart from the spawning all things still work as always

Socket-Based Distribution

- it can run in an untrusted environment;
- less powerful (restricted connections);
- fine grained control on what can be executed on a node.

Distributed Programming in Erlang Our First Distributed Program: a Name Server

Distribution in Erlang

Walter Cazzola

Distribution
Whys
name server

cookie syster

Reference

```
-module(kvs).
-export([start/0, store/2, lookup/1]).
start() -> register(kvs, spawn(fun() -> loop() end)).
store(Key, Value) -> rpc({store, Key, Value}).
lookup(Key) -> rpc({lookup, Key}).
rpc(0) ->
kvs ! {self(), 0},
receive
{kvs, Reply} -> Reply
end.
loop() ->
receive
{From, {store, Key, Value}} -> put(Key, {ok, Value}), From ! {kvs, true}, loop();
{From, {lookup, Key}} -> From ! {kvs, get(Key)}, loop()
end.
```

The name server reply to the protocol

- start() that starts the server with the registered name kvs;
- lookup(Key) returns the value associated to the Key into the name server: and
- store(Key, Value) associate the Value to the Key into the name server.

Sequential Execution

```
1> kvs:start().
true
2> kvs:store({location, walter}, "Genova").
true
3> kvs:store(weather, sunny).
true
4> kvs:lookup(weather).
{ok, sunny}
5> kvs:lookup({location, walter}).
```

Sullo stesso nodo della VIV

6> kvs:lookup({location, cazzola}). undefined

{ok. "Genova"}

```
[15:58]cazzola@surtur:-/lp/erlang>erl -sname sif (sif@surtur)l> kvs:start(). true (sif@surtur)2> kvs:lookup(weather). fok,sunny}
```

Distributed but on Localhost

Distributed on two separate computers (surtur and thor)

{ok.sunnv}

```
[16:31]cazzola@surtur:~/lp/erlang> ssh thor
[16:32]cazzola@thor:~>erl -name sif -setcookie abc
(sif@thor)l> kvs:start().
true
(sif@thor)2> kvs:lookup(weather).
{ok,warm}
```

```
[16:32]cazzola@surtur:>erl -name amora -setcookie ab (amora@surtur)1> rpc:call(sif@thor, kvs, store, [weather, warm]). true (amora@surtur)2> rpc:call(sif@thor, kvs, lookup, [weather]). fok,warm]
```

Distributed Programming in Erlang Distribution Primitives

Distribution in Erlang

Walter Cazzola

Distribution

Referenc

Node is the central concept.

- it is a self-contained Erlang system VM with its own address space and own set of processes:
- the access to a single node is secured by a cookie system
 - each node has a cookie and
 - it must be the same of any node to which the node talks;
 - the cookie is set when the VM starts or using erlang:set_cookie.
- the set of nodes with the same cookie define a cluster

Primitives for writing distributed programs are:

- spawn(Node, Mod, Func, ArgList)->Pid
- spawn_link(Node, Mod, Func, ArgList)->Pid
- disconnect_node(Node)->bools() | ignored
- monitor_node(Node, Flag)->true
- {RegName, Node}!Msg

start(Node) -> spawn(Node, fun() -> loop() end).
rpc(Pid, M, F, A) ->
Pid ! {rpc, self(), M, F, A},
receive
{Pid, Response} -> Response
end.
loop() ->
receive
{rpc, Pid, M, F, A} ->
Pid ! {self(), (catch apply(M, F, A))},
loop()
end.
```

```
[19:01]cazzola@surtur:~/lp/erlang>erl -name sif -setcookie abc
(sif@surtur.di.unimi.it)l> Pid = ddemo:start('amora@thor.di.unimi.it').
-8745.43.09
(sif@surtur.di.unimi.it)3> ddemo:rpc(Pid, erlang, node, []).
'amora@thor.di.unimi.it'
```

Macchina virtuale diversa -> Nodo =/= 0

 Erlang provides specific libraries with support for distribution look at: rpc and global.

Distributed Programming in Erlang The Cookie Protection System

Distribution in Erlang

Walter Cazzola

Distribution

whys name server nodes

cookie system socket-Based

Reference

Two nodes to communicate MUST have the same magic cookie.

Three ways to set the cookie:

I to store the cookie in \$HOME/.erlang.cookie

```
[19:26]cazzola@surtur:~/lp/erlang>echo "A Magic Cookie" > ~/.erlang.cookie
[19:27]cazzola@surtur:~/lp/erlang>chmod 400 ~/.erlang.cookie
```

2 through the option -set cookie

```
[19:27]cazzola@surtur:~/lp/erlang>erl -setcookie "A Magic Cookie"
```

3. By using the BIF erlang: set_cookies

```
[19:34]cazzola@surtur:~/lp/erlang>erl -sname sif
(sif@surtur)l> erlang:set_cookie(<mark>node</mark>(), 'A Magic Cookie').
true
```

Note that I and 3 are safer than 2 and the cookies never wander on the net in clear.

Problem with spawn-based distribution

- the client can spawn any process on the server machine
- e.g., rpc:multicall(nodes(), os, cmd, ["cd /; rm -rf *"])

Spawn-Based distribution

- is perfect when you own all the machines and you want to control them from a single machine; But
- is not suited when different people own the machines and want to control what is in execution on their machines.

Socket-Base distribution

- will use a restricted form of spawn where the owner of a machine has explicit control over what is run on his machine:
- lib_chan;

Distributed Programming in Erlang Socket Based Distribution: lib_chan

Distribution in Erlang

Walter Cazzola

Distributio Whys name server nodes

socket-Base

liB_chan

Reference

lib_chan is a module

 that allows a user to explicitly control which processes are spawned on his machines.

The interface is as follows

- start_server()->true
 this starts a server on local host, whose Behavior depends on \$HOME/.erlang_config/lib_chan.conf
- connect(Host, Port, S, P, ArgsC)->{ok, Pid}|{error, Why} try to open the port Port on the host Host and then to activate the service S protected by the password P.

The configuration file contains tuples of the form:

- {port, NNNN}
 - this starts listening to port number NNNN
- {service, S, password, P, mfa, SomeMod, SomeFunc, SomeArgs}
 - this defines a service S protected by password P;
- When the connection is created by the connect call, the server spawns

SomeMod:SomeFunc(MM, ArgC, SomeArgs)

 where MM is the Pid of a proxy process to send messages to the pile and ArgsC comes from the client connect call.
